Cheat Sheet: Google Refine Expression Language (GREL)

A more complete reference is available at https://github.com/OpenRefine/OpenRefine/wiki/Google-refine-expression-language. For a complete list of GREL functions, see https://github.com/OpenRefine/OpenRefine/wiki/GREL-Functions.

Function	What it does	What it returns	Parameters	Example
<pre>value.match(/regex/) value.match(/regex/)[index] value.match("string") value.match("string")[index]</pre>	Attempts to match the regular expression regex or string string with value. Use /.*regex.*/ to match a partial string.	An array (even if only one match is found). If [index] is present, returns the corresponding string within the array.	<pre>regex = regular expression to match against index = index of a string within the array</pre>	<pre>value = "The cat can't lay on the cot" value.match(/c.t/) → ["cat", "cot"] value.match(/c.t/)[0] → "cat"</pre>
<pre>value.contains(/regex/) value.contains("string")</pre>	Determines whether value contains the regular expression regex or the string string.	A Boolean (true or false).	<pre>regex = regular expression to search</pre>	value = "coffee and tea and chai and mate" value.contains("and") → TRUE
<pre>value.replace(t, u) If t is a regular expression, use /(t)/</pre>	Returns value with all occurrences of the string or regular expression t replaced with the string u.	A string.	<pre>t = string or regex to replace u = string or regex that replaces t</pre>	value = "coffee and tea and chai and mate" value.replace(" and ", ", ") → "coffee, tea, chai, mate"
<pre>value.trim()</pre>	Removes any leading or trailing white space value.	A string.	n/a	value = " coffee " value.trim() → "coffee"
value.length()	String: Returns the length of value. Array: Returns the number of terms in the array value.	A number.	n/a	<pre>value = "coffee" value.length() → 6 value = ["coffee", "tea"] value.length() → 2</pre>
<pre>value.split(delim) value.split(delim)[index]</pre>	Splits string value into an array, breaking at each instance of the string delimiter delim.	An array. If [index] is present, returns the corresponding string within the array.	<pre>delim = delimiter between array elements index = index of a string within the array</pre>	<pre>value = "coffee, tea, chai, mate" value.split(", ") → ["coffee", "tea", "chai", "mate"] value.split(", ")[-1] → "mate"</pre>
value.join(separator)	Joins the elements in the array value into a string with connector separator.	A string.	<pre>separator = the link used to join array elements into a string</pre>	value = ["coffee", "tea", "chai", "mate"] value.join(" AND ") → "coffee AND tea AND chai AND mate"

<pre>value.slice(x, y)</pre>	String: Gives each character in value an index as in an array, and returns the part of this array with index x up to but not including index y. Array: Returns the elements of an array from index x up to but not including index y.	String: a string. Array: an array.	<pre>x = index at which to start slice y = index before which to stop slice</pre>	<pre>value = "coffee" value.slice(1, 4) → "off" value = ["coffee", "tea", chai", "mate"] value.slice(0, 2) → ["coffee", "tea", "chai"]</pre>
<pre>value.partition(fragment) value.partition(fragment)[index] value.partition(fragment, true) = omits fragment from returned array</pre>	Returns an array consisting of the part of value before the first occurrence of fragment, fragment, and the part of value after the first occurrence of fragment.	An array with three terms. If [index] is present, returns the corresponding string within the array.	<pre>fragment = the substring or regular expression around which value is partitioned index = index of a string within the array</pre>	<pre>value = "coffee and tea and chai" value.partition(" and ") → ["coffee", " and ", "tea and chai"] value.partition(" and ")[1] → " and "</pre>
<pre>value.rpartition(fragment) value.rpartition(fragment)[index] value.rpartition(fragment, true) = omits fragment from returned array</pre>	Returns an array consisting of the part of value before the last occurrence of fragment, fragment, and the part of value after the last occurrence of fragment.	An array with three terms. If [index] is present, returns the corresponding string within the array.	<pre>fragment = the substring or regular expression around which value is partitioned index = index of a string within the array</pre>	<pre>value = "coffee and tea and chai" value.rpartition(" and ") → ["coffee and tea", " and ", "chai"] value.rpartition(" and ")[0] → "coffee and tea"</pre>
value.reverse()	Reverses the order of the elements in the array value.	An array.	n/a	<pre>value = ["coffee", "tea", "chai", "mate"] value.reverse() → ["mate", "chai", "tea", "coffee"]</pre>
not(booleanexp)	Returns "TRUE" if the value of booleanexp is false	A Boolean (true or false).	<pre>booleanexp = a function or expression that returns TRUE or FALSE</pre>	value = "coffee" not(value.contains("a")) → TRUE
